VEHICLE SENSOR SYSTEMS **INSTALLATION/OPERATION**

MODEL D-376

System Description

The Vehicle Sensor Systems use a passive sensor that detects changes in the natural magnetic field caused by moving ferrous metal objects such as cars, trucks or buses. The sensor can be buried in dirt adjacent to a paved roadway or placed in concrete or asphalt directly under the path of the vehicle. The roughly circular detection area depends on the size and speed of the vehicle - larger vehicles and faster speeds result in a larger detection area. Up to five sensors can be connected to one Signal Processor to expand the detection area. A sensor can be located up to 5,000 feet (1,520M) from the Signal Processor. An X10 Alarm Interface Module can be connected to the Sensor System and an X10 Chime will provide audible indication of sensor activation. The system will not detect the presence of a vehicle or object, and should never be used as a safety device.

I. Installation Considerations

A. General

1. The standard sensor is furnished with 50, 100 or 150 feet of cable attached. If additional cable is required, order a Custom Length Sensor. Splices in the cable should be avoided if at all possible. If a splice is absolutely essential, use a good quality direct burial waterproof epoxy splice.

2. In order to avoid possible nuisance tripping of the Sensor System, do not install the sensor or sensor cable within about 8 feet of power lines, mercury lights, electric motors or intermittent pumps. It is important to stay as far away as possible from utility lines, transformers or electrical transients.

3. Remember that the mass and speed of vehicles results in a relatively large diameter detection area (See Figure 4). The sensor should not be installed closer than about 30 feet from a busy residential road, about 40 feet from truck traffic, and about 100 feet from railroad tracks.

4. It is essential that the waterproof integrity of the sensor/direct burial cable assembly is maintained. A nicked or crushed cable jacket may allow moisture to enter the cable or sensor, resulting in intermittent and unreliable operation. If a splice is required, use a waterproof epoxy splice, and follow the provided instructions carefully.

5. In order to protect the cable from burrowing critters (moles, etc.), we recommend you run the cable in thick-wall plastic conduit about 18" deep. This will also offer some protection from rototillers and irrigation line trenchers. If the sensor or cable is to be buried in dirt or gravel, the use of plastic conduit will prevent sharp stones from puncturing the cable jacket.

6. The Signal Processor must have a good earth ground in order to provide reliable operation. A metal cold water pipe (street side) or a 5 foot copper rod will provide the best results.

B. Installation Adjacent to a Driveway

1. Determine the optimum placement by laying the sensor on the ground, turning the Signal Processor sensitivity ("GAIN") all the way down, and driving past the sensor at the probable vehicle speed and line of travel (See Figure 4). Gradually increase the sensitivity and/or adjust the sensor location for desired results. Keep the sensitivity as low as possible to avoid nuisance tripping. Bury the sensor about 6 inches (15cm) deep, parallel to the line of travel of the vehicle.

2. If the sensor is put in conduit (1½ inch ID), keep it stationary within the conduit with foam, sponge or tape.

C. Installation In a Driveway

1. The sensor is placed in the middle of the driveway, perpendicular to the line of travel of the vehicles. It should be about 1 inch under the surface of cement, and about 2 inches under asphalt. It can be positioned properly before the driveway is poured or paved, or an existing driveway can be cut to accommodate the sensor and cable.

2. The sensor and cable should be enclosed in plastic pipe to facilitate replacement if required. Again, ensure the sensor is stationary within the pipe.

3. If the driveway is a two-car driveway, two sensors wired in series may be necessary for complete coverage; see Figure 3.

D. Other Applications

The Vehicle Sensor System can be used for other applications and in other physical configurations (see Figure 2 for example). Contact ***MFMsensors, Inc.*** for advice.

II. Installation Instructions

A. Bench Testing

1. Connect AC Power to the processor using the step-down transformer (120VAC to 12VAC) provided. The processor can also be powered by 12-14VDC.

2. Connect the sensor to the processor, and adjust the "GAIN" control CCW (minimum gain).

3. Connect an ohmmeter between the "N/O" and "COM" terminals of the relay. The ohmmeter will read an open until the sensor is activated, at which time it will read less than 10 ohms.

4. After power has been applied for at least three minutes, move the sensor at least 4 feet away from the processor. Activate the sensor by waving a metal object (screwdriver, wrench, etc.) down its length and about two inches away. Verify relay closure with the ohmmeter.

B. Field Testing

1. Connect the sensor(s) to the processor. If more than one sensor is to be used (up to 5 sensors with a total length of 5,000 feet can be supported by one processor), connect them as shown in Figure 3.

2. Connect power to the processor, and allow at least three minutes before proceeding.

3. Place the sensor(s) on the ground in the desired location. Figure 4 shows the approximate coverage pattern for a single sensor.

4. Set the "GAIN" control fully counter-clockwise to minimum gain. Drive past the sensor(s) at the slowest probable vehicle speed. Gradually increase sensitivity ("GAIN") until the sensor(s) consistently detects vehicle movement as indicated by relay closure. Be sure the detection range extends to the furthest edge of the desired protected area. **Do not use more sensitivity than is necessary to ensure reliable vehicle detection.** If the detection area is too small, enlarge it by adding one or more sensors in series (see Figure 3). If the detection area is too large, move the sensor(s) farther from the vehicle path.

C. Installation

1. Review the **Installation Considerations** on the first page of this manual before final installation.

2. Install the processor in an inside location close to a 120VAC outlet and to a good earth ground. Use at least #16 copper wire for the ground connection. Avoid areas close to large motors, electrical machinery, RF garage door openers, etc.

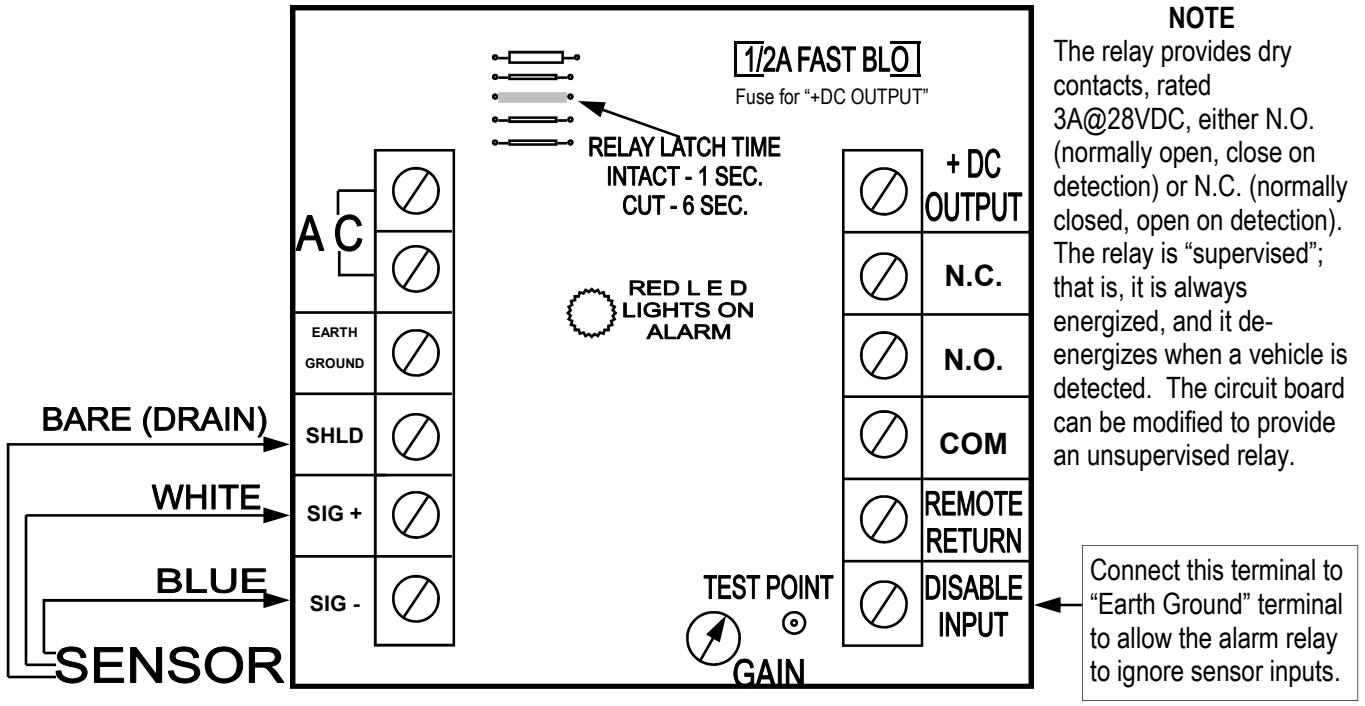

Figure 1 - Model D-376

3. Prepare the trench, and lay the sensor and cable in the trench. Do not run the sensor cable in the same trench with electrical service cable. Be careful not to damage the sensor cable during installation and burial.

4. Field test the system (Par IIB) again to ensure proper operation, then carefully backfill the trench.

5. Set the latch time of the relay as required - see Figure 1. The latch time also controls the duration of the voltage at the "+DC OUTPUT" and "REMOTE RETURN" terminals.

III. Troubleshooting

A. False Tripping

1. There are two basic causes for false tripping in the Vehicle Sensor System - those related to the operating environment, and those related to failure of the sensor or processor. False tripping related to the operating environment is usually caused by faulty grounding, power lines or transformers too close to the sensor or cable, or detection of fast moving vehicles outside the intended sensing area of the sensor. Carefully check these possibilities before assuming sensor or processor malfunction.

2. Most false tripping attributable to the Sensor System is caused by moisture in the sensor or sensor cable. This moisture can enter the sensor from a small nick in the cable during installation or during grounds maintenance. This problem is difficult to verify with an ohmmeter. Check the sensors and processor by performing the steps below. If the problem is not apparent from these tests, then it is usually safe to assume that the sensor and/or cable has moisture in it.

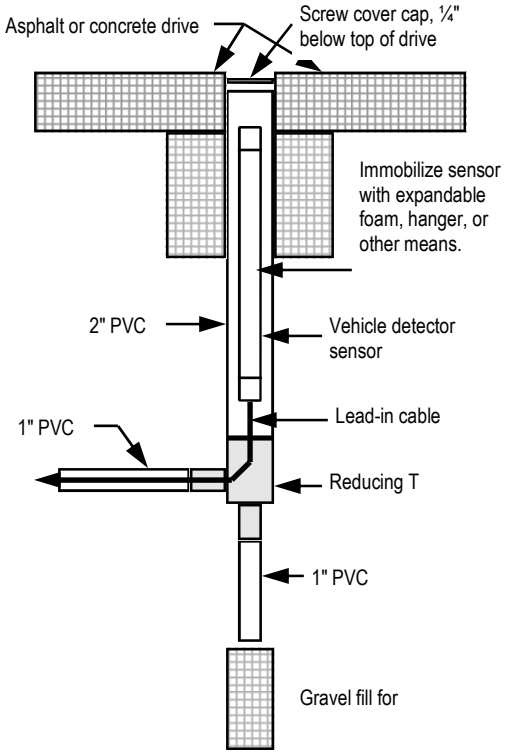

Figure 2 - Vertical Mounting (not to scale)

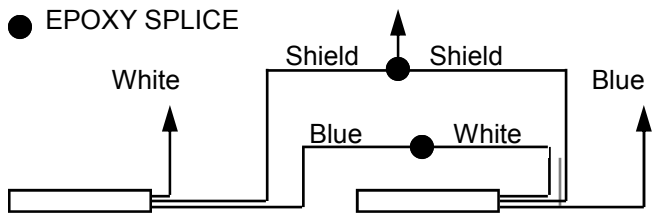

Figure 3-Extending Sensor Range

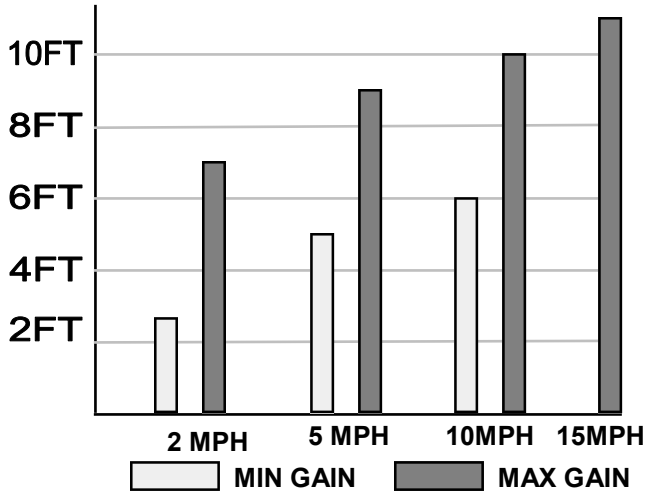

Figure 4 - Approximate Detection Radius

3. Separate sensor problems from processor problems by disconnecting all three sensor wires from the processor and turning the "GAIN" full CW. If the processor trips with the sensor disconnected, the problem is with the processor or input power. **Note: It is normal for the unit to trip when the sensor terminals are touched.**

B. Testing the Sensors

1. Disconnect the sensor leads from the processor.

2. Using a good quality ohmmeter on the highest ohms scale (must be 20Megohms or higher), measure the resistance between the sensor shield (bare) wire, and first the sensor white wire and then the sensor blue wire. The ohmmeter indication should be infinity (totally open) for both measurements. If it is not, the cable either contains moisture or has been partially crushed.

3. Measure the resistance between the sensor white wire and the sensor blue wire. It should be 750 ohms ± 10% . If it is not, the sensor is defective.

If there are multiple sensors connected in series, the resistance at the processor end should be the number of sensors times 750, plus or minus 10%.

C. Testing the Processor

1. Disconnect the sensor (all three wires) from the processor.

2. Check to be sure the input voltage is about 12VAC (or not lower than 12VDC) at the "AC" input.

3. Turn the "GAIN" control about mid position. Momentarily short "SIG +" to "SHLD". The relay should click and the LED should illuminate. If neither happens the processor is faulty.

4. Use a high input impedance DC voltmeter (a digital voltmeter is preferred) to measure the DC voltage between the "SHLD" (-) and "SIG +" (+), and between "SHLD" and "SIG -". This voltage should be between about 2.4 and 2.6VDC. If this voltage is very low, or if there is no voltage reading, the processor is faulty.

5. Connect the DC voltmeter between the "+DC OUTPUT" and "REMOTE RETURN" terminals. When the processor is tripped, this voltage is about 17VDC. If it is not, check the fuse. If the fuse is open, replace it with a 1/2A fast blow and recheck the voltage. If there is no voltage and the fuse is good (and the processor input voltage is good), the board is faulty.

6. Check the DC voltage between the silver spot marked "T.P." (just above and to the right of the "GAIN" control) and "GND". With the sensor disconnected and the "GAIN" control fully clockwise (maximum sensitivity) this voltage should be between 2.4 to 2.6VDC and steady (allow about 30 seconds for the voltage to settle out). If the voltage is not within these limits, or is not steady, the processor is faulty.

7. If the processor relay cycles every second or so with the sensor connected, the problem may be an open sensor cable shield wire. To test this, disconnect all three wires of the sensor. If the cycling stops, look for an open in the shield at a splice or at the processor end. Be sure to ohm out the sensor (par B).

Call MFMsensors, 800-500-6367, for further assistance. Please do not return equipment without a Return Authorization Number and return shipping instructions.

REPLACEMENT ASSEMBLIES

D909 Electronic Circuit Board
D200-XXX Sensor Sensor ("XXX" is number of feet of direct burial cable attached)
A901 Transformer, Plug In, 120VAC/12VAC, 20VA

SPECIFICATIONS

Input Power.....12VAC or 12VDC	Operating Current.....60ma AC, 35ma DC
Relay Contact Rating.....3A @ 28VDC	Relay Latch Time.....Approx. 1 sec. or 6 sec.
Processor Temp. Range.....0 to 120F (-18 to 49C)	Sensor Temp. Range.....-30 to 150F (-34 to 66C)
+ DC Output.....Approx. 17VDC, Unreg.	Sensor Size.....17.5" x 1.25" Diameter

Manufactured, sold and serviced under an exclusive licensing agreement with Racon®. Made in the USA.
